

Repeated-Measures ANOVA

PSYC 300B - Lecture 2
Dr. J. Nicol

Repeated-Measures ANOVA

- In a repeated-measures design we obtain scores from each participant on more than two occasions
- A repeated-measures ANOVA is like a dependent t -test that is used when more than two means are being compared
- Comparisons are made of scores across time within the same subject—so often referred to as a within-subjects design

Advantages and Disadvantages

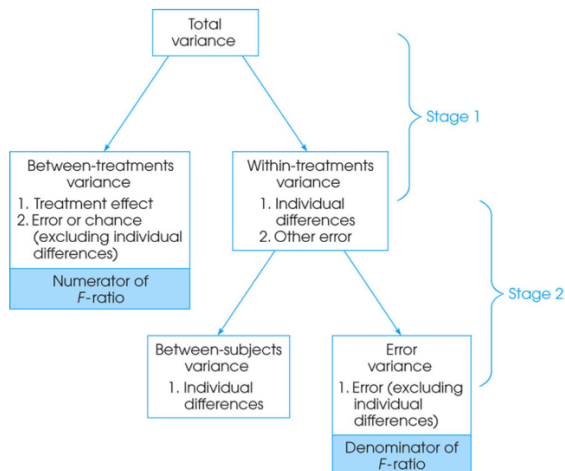

- The primary advantage of a repeated-measure design is that it reduces or eliminates problems caused by individual differences
- Repeated-measures ANOVA allows us to assess individual differences and separate them from the error term (individual differences are a type of systematic variance)
- By removing individual differences, we reduce unsystematic variance (denominator) and in turn increase the chance of finding a significant result
- A repeated-measures design typically requires fewer subjects than a between-groups design

Advantages and Disadvantages

- The repeated-measures design is especially well suited for studying development, or other changes that take place over time (e.g., longitudinal studies)
- Practice effects: participants may gain experience during the first treatment condition, and this may help their performance in subsequent treatments
- One way to deal with time-related factors and order effects is to counterbalance the order of presentation of treatments
- In most cases the advantages outweigh the disadvantages (Howell, 2017)

Assumptions

- Normality within conditions
- Sphericity (homogeneity of variance)—correlations among pairs of conditions of the independent variable are constant
- This is a rather stringent assumption and one that probably is violated at least as often as it is met, and the test is not seriously affected unless the assumption is seriously violated (Howell, 2017)

Calculating Sum of Squares

$$SS_{TOTAL} = \sum (X - M_{GRAND})^2$$

$$SS_{BETWEEN} = n \sum (M_{GROUP} - M_{GRAND})^2$$

$$SS_{SUBJECTS} = k \sum (M_{SUBJECT} - M_{GRAND})^2$$

$$SS_{ERROR} = SS_{TOTAL} - SS_{BETWEEN} - SS_{SUBJECTS}$$

Calculating Degrees of Freedom

$$df_{TOTAL} = N - 1$$

$$df_{BETWEEN} = k - 1$$

$$df_{SUBJECTS} = n - 1$$

$$df_{ERROR} = df_{TOTAL} - df_{BETWEEN} - df_{SUBJECTS}$$

Calculating Mean Squares

$$MS_{BETWEEN} = \frac{SS_{BETWEEN}}{df_{BETWEEN}}$$

$$MS_{ERROR} = \frac{SS_{ERROR}}{df_{ERROR}}$$

Calculating the F -Ratio

$$F = \frac{MS_{BETWEEN}}{MS_{ERROR}}$$

$$F_{CRITICAL} = (df_{BETWEEN}, df_{ERROR})$$

Post-Hoc Tests

- When the assumption of sphericity is not violated Tukey's *HSD* can be used (Field, 2013)
- For a repeated-measures ANOVA, MS_{ERROR} is a correct estimate of the standard error, so we can run the Fisher's *LSD* as if the means were from independent samples (Howell, 2014)

Post-Hoc Tests

$$\text{Fisher's LSD: } t = \frac{M_1 - M_2}{\sqrt{\left(\frac{MS_{ERROR}}{n_1} + \frac{MS_{ERROR}}{n_2}\right)}}$$

$$\text{Tukey's HSD} = q \sqrt{\frac{MS_{ERROR}}{n}}$$

Effect Size Measures

$$\eta^2 = \frac{SS_{BETWEEN}}{SS_{TOTAL} - SS_{SUBJECTS}}$$

$$\omega^2 = \frac{\left[\frac{k-1}{nk} (MS_{BETWEEN} - MS_{ERROR}) \right]}{MS_{ERROR} + \frac{MS_{SUBJECTS} - MS_{ERROR}}{k} + \left[\frac{k-1}{nk} (MS_{BETWEEN} - MS_{ERROR}) \right]}$$

$$d = \frac{M_1 - M_2}{\sqrt{MS_{ERROR}}}$$

Conduct a hypothesis test ($\alpha = .05$) to determine if there is a significant treatment effect. Perform post-hoc tests and report effect sizes

	Pre	Post	Follow-up
	6	8	10
	5	5	5
	1	2	3
	0	1	2

Pre	Post	Follow-up	
6	8	10	$M_{S1} = 8$
5	5	5	$M_{S2} = 5$
1	2	3	$M_{S3} = 2$
0	1	2	$M_{S4} = 1$
$M_{PRE} = 3$	$M_{POST} = 4$	$M_{FOLLOW} = 5$	$M_{GRAND} = 4$

- $H_0: \mu_{\text{TIME1}} = \mu_{\text{TIME2}} = \mu_{\text{TIME3}}$
- $H_1: \text{not all the } \mu\text{'s are equal}$
- $SS_{\text{TOTAL}} = \sum(X - M_{\text{GRAND}})^2 = 102$
- $SS_{\text{BETWEEN}} = n\sum(M_{\text{GROUP}} - M_{\text{GRAND}})^2 = 4[(3-4)^2 + (4-4)^2 + (5-4)^2] = 8$
- $SS_{\text{SUBJECTS}} = k\sum(M_{\text{SUBJECT}} - M_{\text{GRAND}})^2$
 - $= 3[(8-4)^2 + (5-4)^2 + (2-4)^2 + (1-4)^2] = 90$
- $SS_{\text{ERROR}} = 102 - 8 - 90 = 4$
- $df_{\text{TOTAL}} = N - 1 = 12 - 1 = 11$
- $df_{\text{BETWEEN}} = k - 1 = 3 - 1 = 2$
- $df_{\text{SUBJECTS}} = n - 1 = 3$
- $df_{\text{ERROR}} = 11 - 2 - 3 = 6$

- $MS_{\text{BETWEEN}} = SS_{\text{BETWEEN}}/df_{\text{BETWEEN}} = 8/2 = 4$
- $MS_{\text{ERROR}} = SS_{\text{ERROR}}/df_{\text{ERROR}} = 4/6 = 0.67$
- $F = MS_{\text{BETWEEN}}/MS_{\text{ERROR}} = 4/0.67 = 6$
- $F(2, 6)_{\text{CRITICAL}} = 5.14$
- Reject H_0 and conclude there is a significant treatment effect across time, $F(2, 6) = 6.0, p < .05, \eta^2 = 0.67$

Source	SS	df	MS	F
Between	8	2	4	6
Within				
Subjects	90	3		
Error	4	6	0.67	
Total	102	11		

- $k = 3$ and $df_{\text{ERROR}} = 6$, so $q = 4.34$
- $HSD = 4.34\sqrt{(0.67/4)} = 1.78$
- $M_{\text{PRE}} - M_{\text{POST}} = 3 - 4 = 1$ ($p > .05$)
- $M_{\text{PRE}} - M_{\text{FOLLOW-UP}} = 3 - 5 = 2$ ($p < .05$); $d = 2/\sqrt{0.67} = 2.44$
- $M_{\text{POST}} - M_{\text{FOLLOW-UP}} = 4 - 5 = 1$ ($p > .05$)
- Scores were significantly higher at follow-up compared to pre-treatment

Conduct a hypothesis test ($\alpha = .05$) to determine if spelling errors decrease as students progress through grades.
Perform post-hoc tests and report effect sizes

4th Grade	5th Grade	6th Grade
4	3	1
8	6	4
5	3	3
